Game Boy: Complete Technical Reference

gekkio https://gekkio.fi March 25, 2024 Revision 144

Preface

Caveat

IMPORTANT: This document focuses at the moment on 1st and 2nd generation devices (models before the Game Boy Color), and some hardware details are very different in later generations.

Be very careful if you make assumptions about later generation devices based on this document!

How to read this document

***** Speculation

This is something that hasn't been verified, but would make a lot of sense.

1 Caveat

This explains some caveat about this documentation that you should know.

Warning

This is a warning about something.

0.1 Formatting of numbers

When a single bit is discussed in isolation, the value looks like this: 0, 1.

Binary numbers are prefixed with 0b like this: 0b0101101, 0b11011, 0b00000000. Values are prefixed with zeroes when necessary, so the total number of digits always matches the number of digits in the value.

Hexadecimal numbers are prefixed with 0x like this: 0x1234, 0xDEADBEEF, 0xFF04. Values are prefixed with zeroes when necessary, so the total number of characters always matches the number of nibbles in the value.

Examples:

4-bit	8-bit	16-bit
→ -1/11	O-DIL	10-01

Binary 0b0101 0b10100101 0b0000101010100101

Hexadecimal 0x5 0xA5 0x0AA5

0.2 Register definitions

Register 0.1: 0x1234 - This is a hardware register definition

R/W-0	R/W-1	U-1	R-0	R-1	R-x	W-1	U-0
VALUE	<1:0>			BIGVAL<7:5>		FLAG	
bit 7	6	5	4	3	2	1	bit 0

Top row legend:

- **R** Bit can be read.
- **W** Bit can be written. If the bit cannot be read, reading returns a constant value defined in the bit list of the register in question.
- **U** Unimplemented bit. Writing has no effect, and reading returns a constant value defined in the bit list of the register in question.
- -n Value after system reset: 0, 1, or x.
- **1** Bit is set.
- Ø Bit is cleared.
- **x** Bit is unknown (e.g. depends on external things such as user input)

Middle row legend:

VALUE<1:0>	Bits 1 and 0 of VALUE
	Unimplemented bit
BIGVAL<7:5>	Bits 7, 6, 5 of BIGVAL
FLAG	Single-bit value FLAG

In this example:

- After system reset, VALUE is 0b01, BIGVAL is either 0b010 or 0b011, FLAG is 0b1.
- Bits 5 and 0 are unimplemented. Bit 5 always returns 1, and bit 0 always returns 0.
- Both bits of VALUE can be read and written. When this register is written, bit 7 of the written value goes to bit 1 of VALUE.
- FLAG can only be written to, so reads return a value that is defined elsewhere.
- BIGVAL cannot be written to. Only bits 5-7 of BIGVAL are defined here, so look elsewhere for the low bits 0-4.

Part I Sharp SM83 CPU core

Introduction

Game Boy SoCs contain a Sharp SM83 CPU core, which is an 8-bit CPU core closely resembling Zilog Z80 and Intel 8080 but is neither.

Simple model

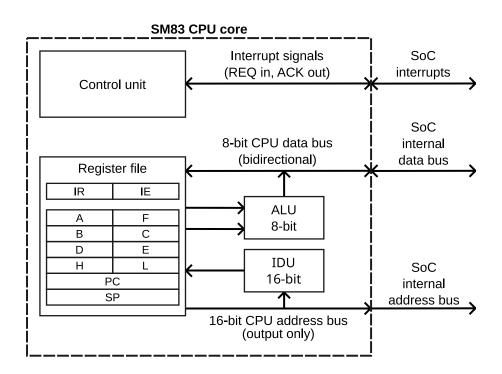

Figure 2.1: Simple model of the SM83 CPU core

Figure 2.1 shows a simplified model of the SM83 CPU core. The core interacts with the rest of the SoC using interrupt signals, an 8-bit bidirectional data bus, and a 16-bit address bus controlled by the CPU core.

The main subsystems of the CPU core are as follows:

Control unit The control unit decodes the executed instructions and generates control signals for the rest of the CPU core. It is also responsible for checking and dispatching interrupts.

Register file The register file holds most of the state of the CPU inside registers. It contains the 16-bit Program Counter (PC), the 16-bit Stack Pointer (SP), the 8-bit Accumulator (A), the Flags register (F), general-purpose register pairs consisting of two 8-bit halves such as BC, DE, HL, and the special-purpose 8-bit registers Instruction Register (IR) and Interrupt Enable (IE).

ALU An 8-bit Arithmetic Logic Unit (ALU) has two 8-bit input ports and is capable of performing various calculations. The ALU outputs its result either to the register file or the CPU data bus.

A dedicated 16-bit Increment/Decrement Unit (IDU) is capable of performing only simple increment/decrement operations on the 16-bit address bus value, but they can be performed independently of the ALU, improving maximum performance of the CPU core. The IDU always outputs its result back to the register file, where it can be written to a register pair or a 16-bit register.

CPU core timing

3.1 Fetch/execute overlap

Sharp SM83 uses a microprocessor design technique known as *fetch/execute overlap* to improve CPU performance by doing opcode fetches in parallel with instruction execution whenever possible. Since the CPU can only perform one memory access per M-cycle, it is worth it to try to do memory operations as soon as possible. Also, when doing a memory read, the CPU cannot use the data during the same M-cycle so the true minimum effective duration of instructions is 2 machine cycles, not 1 machine cycle.

Every instruction needs one machine cycle for the fetch stage, and at least one machine cycle for the decode/execute stage. However, the fetch stage of an instruction always overlaps with the last machine cycle of the execute stage of the previous instruction. The overlapping execute stage cycle may still do some work (e.g. ALU operation and/or register writeback) but memory access is reserved for the fetch stage of the next instruction.

Since all instructions effectively last one machine cycle longer, fetch/execute overlap is usually ignored in documentation intended for programmers. It is much easier to think of a program as a sequence of non-overlapping instructions and consider only the execute stages when calculating instruction durations. However, when emulating a SM83 CPU core, understanding and emulating the overlap can be useful.

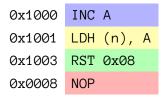

Warning

Sharp SM831x is a family of single-chip SoCs from Sharp that use the SM83 CPU core, and their datasheet [1] includes a description of fetch/execute overlap. However, the description is not completely correct and can in fact be misleading.

For example, the timing diagram includes an instruction that does not involve opcode fetch at all, and memory operations for two instructions are shown to happen at the same time, which is not possible.

Fetch/execute overlap timing example

Let's assume the CPU is executing a program that starts from the address 0x1000 and contains the following instructions:

The following timing diagram shows all memory operations done by the CPU, and the fetch and execute stages of each instruction:

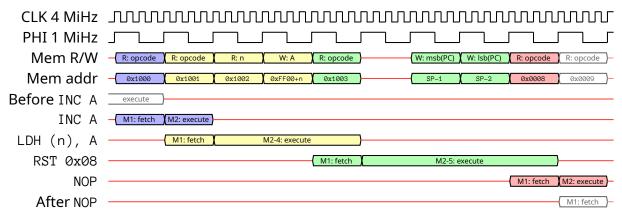

Figure 3.2: Fetch/execute overlap example

Sharp SM83 instruction set

4.1 Overview

CB opcode prefix

Undefined opcodes

4.2 8-bit load instructions

LD r, r': Load register (register)

Load to the 8-bit register r, data from the 8-bit register r'.

Opcode ObO1xxxyyy/various Duration 1 machine cycle Length 1 byte: opcode Flags - Simple timing and pseudocode

```
M-cycle — M1 — Mem R/W — Opcode — opcode = read_memory(addr=PC); PC = PC + 1

if opcode == 0x41: # example: LD B, C

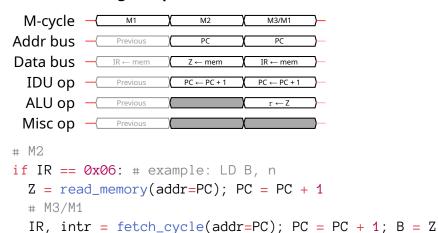

B = C
```

LD r, n: Load register (immediate)

Load to the 8-bit register r, the immediate data n.

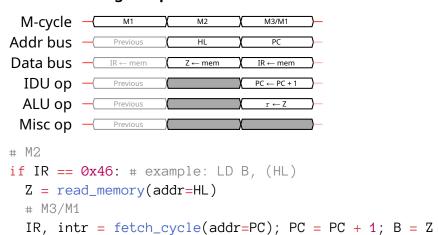

```
Opcode 0b00xxx110/various
Length 2 bytes: opcode + n
Simple timing and pseudocode
```

```
Duration 2 machine cycles Flags -
```

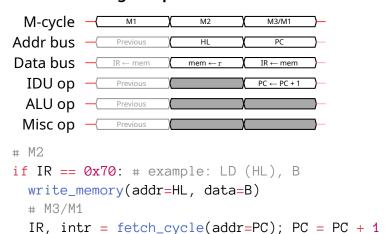

LD r, (HL): Load register (indirect HL)

Load to the 8-bit register r, data from the absolute address specified by the 16-bit register HL.

LD (HL), r: Load from register (indirect HL)

Load to the absolute address specified by the 16-bit register HL, data from the 8-bit register r.

LD (HL), n: Load from immediate data (indirect HL)

Load to the absolute address specified by the 16-bit register HL, the immediate data n.

```
M-cycle M1 M2 M3

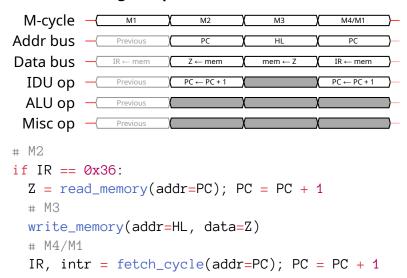

Mem R/W Opcode R:n W:n

opcode = read_memory(addr=PC); PC = PC + 1

if opcode == 0x36:

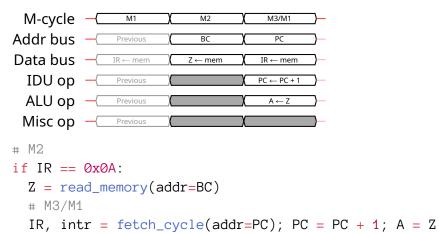

n = read_memory(addr=PC); PC = PC + 1

write_memory(addr=HL, data=n)
```

LD A, (BC): Load accumulator (indirect BC)

Load to the 8-bit A register, data from the absolute address specified by the 16-bit register BC.

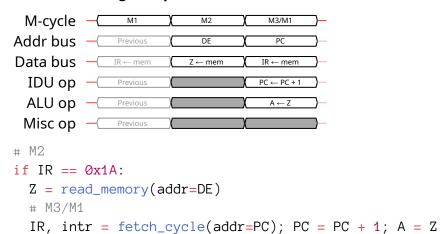

LD A, (DE): Load accumulator (indirect DE)

Load to the 8-bit A register, data from the absolute address specified by the 16-bit register DE.

Detailed timing and pseudocode

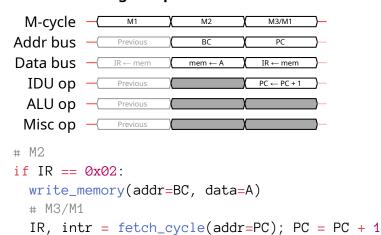

A = read_memory(addr=DE)

if opcode == 0x1A:

LD (BC), A: Load from accumulator (indirect BC)

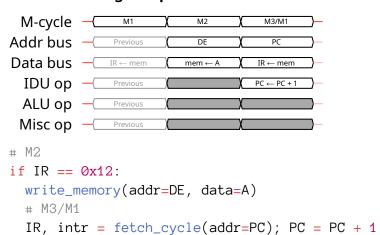

Load to the absolute address specified by the 16-bit register BC, data from the 8-bit A register.

LD (DE), A: Load from accumulator (indirect DE)

Load to the absolute address specified by the 16-bit register DE, data from the 8-bit A register.

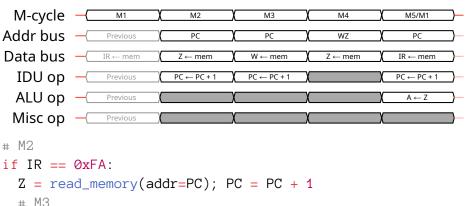

Opcode 0b00010010/0x12 Duration 2 machine cycles Length 1 byte: opcode Flags - Simple timing and pseudocode

LD A, (nn): Load accumulator (direct)

Load to the 8-bit A register, data from the absolute address specified by the 16-bit operand nn.

Opcode 0b11111010/0xFA Duration 4 machine cycles Length 3 bytes: opcode + LSB(nn) + MSB(nn) Flags - Simple timing and pseudocode

```
Z = read_memory(addr=PC); PC = PC + 1
# M3
W = read_memory(addr=PC); PC = PC + 1
# M4
Z = read_memory(addr=WZ)
# M5/M1
IR, intr = fetch_cycle(addr=PC); PC = PC + 1; A = Z
```

LD (nn), A: Load from accumulator (direct)

Load to the absolute address specified by the 16-bit operand nn, data from the 8-bit A register.

LDH A, (C): Load accumulator (indirect 0xFF00+C)

M2

if IR == 0xF2:

M3/M1

Load to the 8-bit A register, data from the address specified by the 8-bit C register. The full 16-bit absolute address is obtained by setting the most significant byte to 0xFF and the least significant byte to the value of C, so the possible range is 0xFF00-0xFFFF.

```

```

LD (nn), SP: Load from stack pointer (direct)

Load to the absolute address specified by the 16-bit operand nn, data from the 16-bit SP register.

Opcode 0b00001000/0x08 **Duration** 5 machine cycles **Length** 3 bytes: opcode + LSB(nn) + MSB(nn) **Flags** Simple timing and pseudocode M-cycle — M1 M2 М3 M4 M5 Mem R/W — opcode R: Z R: W W: SPH W: SPL opcode = read_memory(addr=PC); PC = PC + 1 if opcode == 0x08: nn_lsb = read_memory(addr=PC); PC = PC + 1 nn_msb = read_memory(addr=PC); PC = PC + 1 nn = unsigned_16(lsb=nn_lsb, msb=nn_msb) write_memory(addr=nn, data=lsb(SP)); nn = nn + 1

Detailed timing and pseudocode

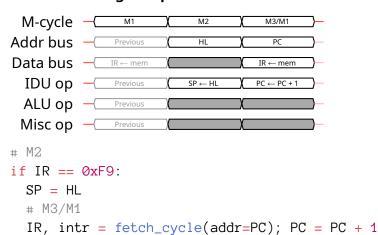

write_memory(addr=nn, data=msb(SP))

```
f IR == 0x08:
Z = read_memory(addr=PC); PC = PC + 1
# M3
W = read_memory(addr=PC); PC = PC + 1
# M4
write_memory(addr=WZ, data=lsb(SP)); WZ = WZ + 1
# M5
write_memory(addr=WZ, data=msb(SP))
# M6/M1
IR, intr = fetch_cycle(addr=PC); PC = PC + 1
```

LD SP, HL: Load stack pointer from HL

Load to the 16-bit SP register, data from the 16-bit HL register.

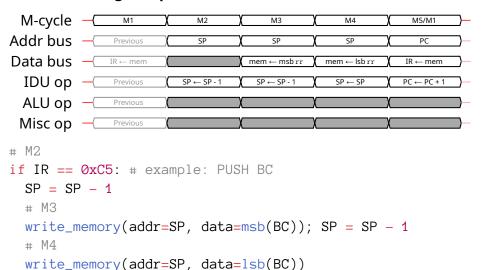

PUSH rr: Push to stack

Push to the stack memory, data from the 16-bit register rr.

Detailed timing and pseudocode

M5/M1

IR, intr = fetch_cycle(addr=PC); PC = PC + 1

POP rr: Pop from stack

Pops to the 16-bit register rr, data from the stack memory.

This instruction does not do calculations that affect flags, but POP AF completely replaces the F register value, so all flags are changed based on the 8-bit data that is read from memory.

Opcode 0b11xx0001/various Length 1 byte: opcode Simple timing and pseudocode **Duration** 3 machine cycles**Flags** See the instruction description

```

JP HL: Jump to HL

Unconditional jump to the absolute address specified by the 16-bit register HL.

Opcode 0b11101001/0xE9
Length 1 byte: opcode
Simple timing and pseudocode

Duration 1 machine cycle
Flags -

```
M-cycle — M1 — Mem R/W — Opcode — Opcode = read_memory(addr=PC); PC = PC + 1 if opcode == 0xE9:
PC = HL
```

Warning

In some documentation this instruction is written as JP [HL]. This is very misleading, since brackets are usually used to indicate a memory read, and this instruction simply copies the value of HL to PC.

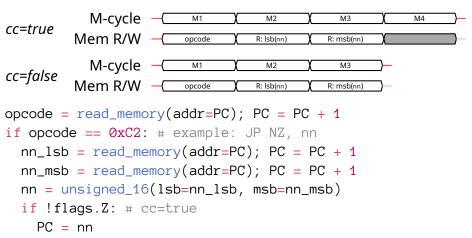

JP cc, nn: Jump (conditional)

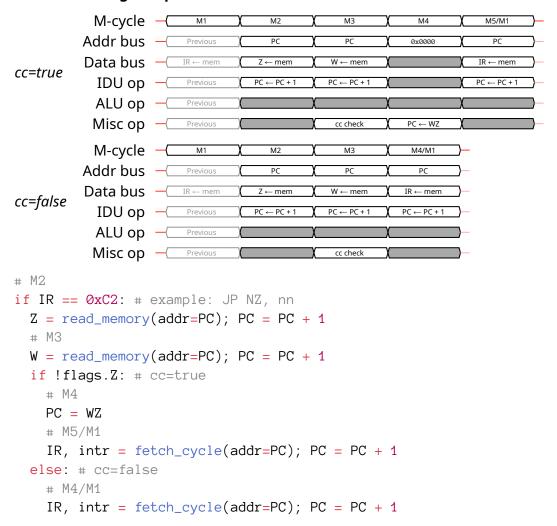

Conditional jump to the absolute address specified by the 16-bit operand nn, depending on the condition cc.

Note that the operand (absolute address) is read even when the condition is false!

Opcode0b110xx010/variousDuration4 machine cycles (cc=true)3 machine cycles (cc=false)

Length 3 bytes: opcode + LSB(nn) + MSB(nn) **Flags Simple timing and pseudocode**

JR e: Relative jump

Unconditional jump to the relative address specified by the signed 8-bit operand e.

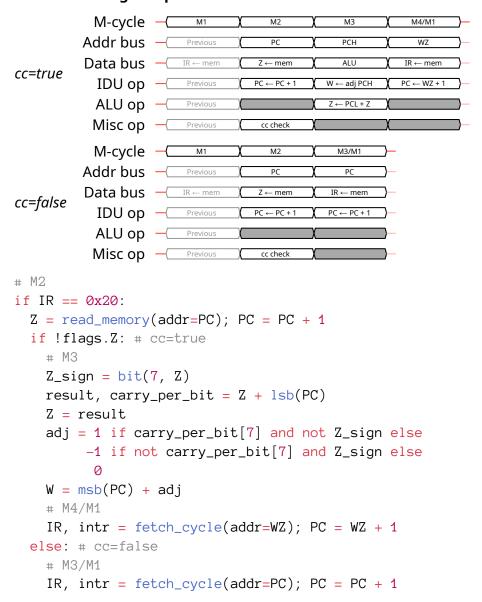

```
M-cycle — M1

Part II Game Boy SoC peripherals and features

Boot ROM

The Game Boy SoC includes a small embedded boot ROM, which can be mapped to the 0x0000-0x00FF memory area. While mapped, all reads from this area are handled by the boot ROM instead of the external cartridge, and all writes to this area are ignored and cannot be seen by external hardware (e.g. the cartridge MBC).

The boot ROM is enabled by default, so when the system exits the reset state and the CPU starts execution from address $0 \times 0 \times 0 \times 0$, it executes the boot ROM instead of instructions from the cartridge ROM. The boot ROM is responsible for showing the initial logo, and checking that a valid cartridge is inserted into the system. If the cartridge is valid, the boot ROM unmaps itself before execution of the cartridge ROM starts at $0 \times 0 \times 1 \times 0$. The cartridge ROM has no chance of executing any instructions before the boot ROM is unmapped, which prevents the boot ROM from being read byte by byte in normal conditions.

Warning

Don't confuse the boot ROM with the additional SNES ROM in SGB/SGB2 that is executed by the SNES CPU.

Register 5.1: 0xFF50 - BOOT - Boot ROM lock register

U	U	U	U	U	U	U	R/W-0
							BOOT_OFF
bit 7	6	5	4	3	2	1	bit 0

bit 7-1 Unimplemented: Ignored during writes, reads are undefined

bit 0 BOOT OFF: Boot ROM lock bit

0b1 = Boot ROM is disabled and 0x0000-0x00FF works normally.

0b0 = Boot ROM is active and intercepts accesses to 0x0000-0x00FF.

BOOT_OFF can only transition from 0b0 to 0b1, so once 0b1 has been written, the boot ROM is permanently disabled until the next system reset. Writing 0b0 when BOOT_OFF is 0b0 has no effect and doesn't lock the boot ROM.

The 1-bit BOOT register controls mapping of the boot ROM. Once 0b1 has been written to it to unmap the boot ROM, it can only be mapped again by resetting the system.

5.1 Boot ROM types

Table 5.1: Summary of boot ROM file hashes

DMG boot ROM

The most common boot ROM is the DMG boot ROM used in almost all original Game Boy units. If a valid cartridge is inserted, the boot ROM scrolls a logo to the center of the screen, and plays a "di-ding" sound recognizable by most people who have used Game Boy consoles.

This boot ROM was originally dumped by neviksti in 2003 by decapping the Game Boy SoC and visually inspecting every single bit.

MGB boot ROM

This boot ROM was originally dumped by Bennvenn in 2014 by using a simple clock glitching method that only requires one wire.

SGB boot ROM

This boot ROM was originally dumped by Costis Sideris in 2009 by using an FPGA-based clock glitching method [2].

SGB2 boot ROM

This boot ROM was originally dumped by gekkio in 2015 by using a Teensy 3.1 -based clock glitching method [3].

Early DMG boot ROM ("DMG0")

Very early original Game Boy units released in Japan (often called "DMG0") included the launch version "DMG-CPU" SoC chip, which used a different boot ROM than later units.

This boot ROM was originally dumped by gekkio in 2016 by using a clock glitching method invented by BennVenn.

DMA (Direct Memory Access)

6.1 Object Attribute Memory (OAM) DMA

OAM DMA is a high-throughput mechanism for copying data to the OAM area (a.k.a. Object Attribute Memory, a.k.a. sprite memory). It can copy one byte per machine cycle without involving the CPU at all, which is much faster than the fastest possible memory routine that can be written with the SM83 instruction set. However, a transfer cannot be cancelled and the transfer length cannot be controlled, so the DMA transfer always updates the entire OAM area (= 160 bytes) even if you actually want to just update the first couple of bytes.

The Game Boy CPU chip contains a DMA controller that coordinates transfers between a **source area** and the **OAM area** independently of the CPU. While a transfer is in progress, it takes control of the source bus and the OAM area, so some precaution is needed with memory accesses (including instruction fetches) to avoid OAM DMA bus conflicts. OAM DMA uses a different address decoding scheme than normal memory accesses, so the source bus is always either the external bus or the video RAM bus, and the contents normally visible to the CPU in the <code>0xFE00-0xFFFF</code> address range cannot be used as a source for OAM DMA transfers.

The upper 8 bits of the OAM DMA source address are stored in the DMA register, while the lower 8 bits used by both the source and target address are stored in the DMA controller and are not accessible directly. A transfer always begins with 0x00 in the lower bits and copies exactly 160 bytes, so the lower bits are never in the 0xA0-0xFF range.

Writing to the DMA register updates the upper bits of the DMA source address and also triggers an OAM DMA transfer request, although the DMA transfer does not begin immediately.

Register 6.1: 0xFF46 - DMA - OAM DMA control register

R/W-x	R/W-x	R/W-x	R/W-x	R/W-x	R/W-x	R/W-x	R/W-x			
	DMA<7:0>									
bit 7	bit 7 6 5 4 3 2 1 bit 0									

bit 7-0 DMA<7:0>: OAM DMA source address

Specifies the top 8 bits of the OAM DMA source address.

Writing to this register requests an OAM DMA transfer, but it's just a request and the actual DMA transfer starts with a delay.

Reading this register returns the value that was previously written to the register. The stored value is not cleared on reset, so the initial value before the first write is unknown and should not be relied on.

Warning

Avoid writing 0xE0-0xFF to the DMA register, because some poorly designed flash carts can trigger bus conflicts or other dangerous behaviour.

OAM DMA address decoding

The OAM DMA controller uses a simplified address decoding scheme, which leads to some addresses being unusable as source addresses. Unlike normal memory accesses, OAM DMA transfers interpret all accesses in the $0\times A000-0\times FFFF$ range as external RAM transfers. For example, if the OAM DMA wants to read $0\times FF00$, it will output $0\times FF00$ on the external address bus and will assert the external RAM chip select signal. The P1 register which is normally at $0\times FF00$ is not involved at all, because OAM DMA address decoding only uses the external bus and the video RAM bus. Instead, the resulting behaviour depends on several factors, including the connected cartridge. Some flash carts are not prepared for this unexpected scenario, and a bus conflict or worse behaviour can happen.

DMA register value	Used bus	Asserted chip select signal
0x00-0x7F	external bus	external ROM (A15)
0x80-0x9F	video RAM bus	video RAM (MCS)
0xA0-0xFF	external bus	external RAM (CS)

Part III Game Boy game cartridges

MBC1 mapper chip

The majority of games for the original Game Boy use the MBC1 chip. MBC1 supports ROM sizes up to 16 Mbit (128 banks of 0x4000 bytes) and RAM sizes up to 256 Kbit (4 banks of 0x2000 bytes). The information in this section is based on my MBC1 research, Tauwasser's research notes [4], and Pan Docs [5].

10.1 MBC1 registers

Caveat

These registers don't have any standard names and are usually referred to using their address ranges or purposes instead. This document uses names to clarify which register is meant when referring to one.

The MBC1 chip includes four registers that affect the behaviour of the chip. Of the cartridge bus address signals, only A13-A15 are connected to the MBC, so lower address bits don't matter when the CPU is accessing the MBC and all registers are effectively mapped to address ranges instead of single addresses. All registers are smaller than 8 bits, and unused bits are simply ignored during writes. The registers are not directly readable.

Register 10.1: 0x0000-0x1FFF - RAMG - MBC1 RAM gate register

U	U	U	U	W-0	W-0	W-0	W-0
					RAMG	(3:0)	
bit 7	6	5	4	3	2	1	bit 0

bit 7-4 Unimplemented: Ignored during writes

bit 3-0 RAMG<3:0>: RAM gate register

0b1010 = enable access to chip RAM

All other values disable access to chip RAM

The RAMG register is used to enable access to the cartridge SRAM if one exists on the cartridge circuit board. RAM access is disabled by default but can be enabled by writing to the 0x0000-0x1FFF address range a value with the bit pattern 0b1010 in the lower nibble. Upper bits don't matter, but any other bit pattern in the lower nibble disables access to RAM.

When RAM access is disabled, all writes to the external RAM area 0xA000-0xBFFF are ignored, and reads return undefined values. Pan Docs recommends disabling RAM when it's not being accessed to protect the contents [5].

***** Speculation

We don't know the physical implementation of RAMG, but it's certainly possible that the 0b1010 bit pattern check is done at write time and the register actually consists of just a single bit.

Register 10.2: 0x2000-0x3FFF - BANK1 - MBC1 bank register 1

U	U	U	W-0	W-0	W-0	W-0	W-1
					BANK1<4:0>		
bit 7	6	5	4	3	2	1	bit 0

bit 7-5 Unimplemented: Ignored during writes

bit 4-0 BANK1<4:0>: Bank register 1

Never contains the value 0600000.

If 0b00000 is written, the resulting value will be 0b00001 instead.

The 5-bit BANK1 register is used as the lower 5 bits of the ROM bank number when the CPU accesses the 0x4000-0x7FFF memory area.

MBC1 doesn't allow the BANK1 register to contain zero (bit pattern 0b00000), so the initial value at reset is 0b00001 and attempting to write 0b00000 will write 0b00001 instead. This makes it impossible to read banks 0x00, 0x20, 0x40 and 0x60 from the 0x4000-0x7FFF memory area, because those bank numbers have 0b000000 in the lower bits. Due to the zero value adjustment, requesting any of these banks actually requests the next bank (e.g. 0x21 instead of 0x20).

Register 10.3: 0x2000-0x3FFF - BANK1 - MBC1 bank register 2

U	U	U	U	U	U	W-0	W-0
						BANK2	<1:0>
bit 7	6	5	4	3	2	1	bit 0

bit 7-2 Unimplemented: Ignored during writes

bit 1-0 BANK2<1:0>: Bank register 2

The 2-bit BANK2 register can be used as the upper bits of the ROM bank number, or as the 2-bit RAM bank number. Unlike BANK1, BANK2 doesn't disallow zero, so all 2-bit values are possible.

Register 10.4: 0x6000-0x7FFF - MODE - MBC1 mode register

U	U	U	U	U	U	U	W-0
							MODE
bit 7	6	5	4	3	2	1	bit 0

bit 7-1 Unimplemented: Ignored during writes

bit 0 MODE: Mode register

0b1 = BANK2 affects accesses to 0x0000-0x3FFF, 0x4000-0x7FFF, 0xA000-0xBFFF

0b0 = BANK2 affects only accesses to 0x4000-0x7FFF

The MODE register determines how the BANK2 register value is used during memory accesses.

Warning

Most documentation, including Pan Docs [5], calls value 0b0 ROM banking mode, and value 0b1 RAM banking mode. This terminology reflects the common use cases, but "RAM banking" is slightly misleading because value 0b1 also affects ROM reads in multicart cartridges and cartridges that have a 8 or 16 Mbit ROM chip.

10.2 ROM in the 0x0000-0x7FFF area

In MBC1 cartridges, the A0-A13 cartridge bus signals are connected directly to the corresponding ROM pins, and the remaining ROM pins (A14-A20) are controlled by the MBC1. These remaining pins form the ROM bank number.

When the 0x0000-0x3FFF address range is accessed, the effective bank number depends on the MODE register. In MODE 0b0 the bank number is always 0, but in MODE 0b1 it's formed by shifting the BANK2 register value left by 5 bits.

When the 0x4000-0x7FFF addess range is accessed, the effective bank number is always a combination of BANK1 and BANK2 register values.

If the cartridge ROM is smaller than 16 Mbit, there are less ROM address pins to connect to and therefore some bank number bits are ignored. For example, 4 Mbit ROMs only need a 5-bit bank number, so the BANK2 register value is always ignored because those bits are simply not connected to the ROM.

	ROM address bits			
Accessed address	Bank ı	number	Address within bank	
	20-19	18-14	13-0	
0x0000-0x3FFF, MODE = 0b0	0b00	0b00000	A<13:0>	
0x0000-0x3FFF, MODE = 0b1	BANK2	0b00000	A<13:0>	
0x4000-0x7FFF	BANK2	BANK1	A<13:0>	

Table 10.1: Mapping of physical ROM address bits in MBC1 carts

ROM banking example 1

Let's assume we have previously written 0x12 to the BANK1 register and 0b01 to the BANK2 register. The effective bank number during ROM reads depends on which address range we read and on the value of the MODE register:

Value of the BANK 1 register 0b10010

Value of the BANK 2 register ∅b<mark>∅1</mark>

Effective ROM bank number

(reading 0x0000-0x3FFF, MODE = 0b00000000 (= 0 = 0x00)

Effective ROM bank number

ROM banking example 2

Let's assume we have previously requested ROM bank number 68, MBC1 mode is 0b0, and we are now reading a byte from 0x72A7. The actual physical ROM address that will be read is going to be 0x1132A7 and is constructed in the following way:

Value of the BANK 1 register 0b00100

Value of the BANK 2 register 0b10

ROM bank number $0b_{1000100}$ (= 68 = 0x44)

Address being read 0b0111 0010 1010 0111 (= 0x72A7)

Actual physical ROM address 0b1 0001 0011 0010 1010 0111 (= 0x1132A7)

10.3 RAM in the 0xA000-0xBFFF area

Some MBC1 carts include SRAM, which is mapped to the 0xA000-0xBFFF area. If no RAM is present, or RAM is not enabled with the RAMG register, all reads return undefined values and writes have no effect.

On boards that have RAM, the A0-A12 cartridge bus signals are connected directly to the corresponding RAM pins, and pins A13-A14 are controlled by the MBC1. Most of the time the RAM size is 64 Kbit, which corresponds to a single bank of 0×2000 bytes. With larger RAM sizes the BANK2 register value can be used for RAM banking to provide the two high address bits.

In MODE 0b0 the BANK2 register value is not used, so the first RAM bank is always mapped to the 0xA000–0xBFFF area. In MODE 0b1 the BANK2 register value is used as the bank number.

	RAM address bits			
Accessed address	Bank number	Address within bank		
	14-13	12-0		
0xA000-0xBFFF, MODE = 0b0	0b00	A<12:0>		
0xA000-0xBFFF, MODE = 0b1	BANK2	A<12:0>		

Table 10.2: Mapping of physical RAM address bits in MBC1 carts

RAM banking example 1

Let's assume we have previously written 0b10 to the BANK2 register, MODE is 0b1, RAMG is 0b1010 and we are now reading a byte from 0xB123. The actual physical RAM address that will be read is going to be 0x5123 and is constructed in the following way:

Value of the BANK 2 register 0b10

Address being read 0b1011 0001 0010 0011 (= 0xB123)

Actual physical RAM address 0b101 0001 0010 0011 (= 0x5123)

10.4 MBC1 multicarts ("MBC1M")

MBC1 is also used in a couple of "multicart" cartridges, which include more than one game on the same cartridge. These cartridges use the same regular MBC1 chip, but the circuit board is wired a bit differently. This alternative wiring is sometimes called "MBC1M", but technically the mapper chip is the same. All known MBC1 multicarts use 8 Mbit ROMs, so there's no definitive wiring for other ROM sizes.

In MBC1 multicarts bit 4 of the BANK1 register is not physically connected to anything, so it's skipped. This means that the bank number is actually a 6-bit number. In all known MBC1 multicarts the games reserve 16 banks each, so BANK2 can actually be considered "game number", while BANK1 is the internal bank number within the selected game. At reset BANK2 is 0b00, and the "game" in this slot is actually a game selection menu. The menu code selects MODE 0b1 and writes the game number to BANK2 once the user selects a game.

From a ROM banking point of view, multicarts simply skip bit 4 of the BANK1 register, but otherwise the behaviour is the same. MODE 0b1 guarantees that all ROM accesses, including accesses to 0x0000-0x3FFF, use the BANK2 register value.

	ROM address bits			
Accessed address	Bank number		Address within bank	
	19-18	17-14	13-0	
0x0000-0x3FFF, MODE = 0b0	0b00	0b0000	A<13:0>	
0x0000-0x3FFF, MODE = 0b1	BANK2	0b0000	A<13:0>	
0x4000-0x7FFF	BANK2	BANK1<3:0>	A<13:0>	

Table 10.3: Mapping of physical ROM address bits in MBC1 multicarts

ROM banking example 1

Value of the BANK 2 register

Let's assume we have previously requested "game number" 3 (= 0b11) and ROM bank number 29 (= 0x1D), MBC1 mode is 0b1, and we are now reading a byte from 0x6C15. The actual physical ROM address that will be read is going to be 0xF6C15 and is constructed in the following way:

0b11

Value of the BANK 1 register 0b11101

ROM bank number $0b_{111101}$ (= 61 = 0x3D)

Address being read 0b0110 1100 0001 0101 (= 0x6C15)

Actual physical ROM address 0b1111 0110 1100 0001 0101 (= 0xF6C15)

Detecting multicarts

MBC1 multicarts are not detectable by simply looking at the ROM header, because the ROM type value is just one of the normal MBC1 values. However, detection is possible by going through BANK2 values and looking at "bank 0" of each multicart game and doing some heuristics based

on the header data. All the included games, including the game selection menu, have proper header data. One example of a good heuristic is logo data verification.

So, if you have a 8 Mbit cart with MBC1, first assume that it's a multicart and bank numbers are 6-bit values. Set BANK1 to zero and loop through the four possible BANK2 values while checking the data at $0 \times 0.0104 - 0 \times 0.0133$. In other words, check logo data starting from physical ROM locations 0×0.0104 , 0×4.0104 , 0×8.0104 , and 0×0.0104 . If proper logo data exists with most of the BANK2 values, the cart is most likely a multicart. Note that multicarts can just have two actual games, so one of the locations might not have the header data in place.

10.5 Dumping MBC1 carts

MBC1 cartridge dumping is fairly straightforward with the right hardware. The total number of banks is read from the header, and each bank is read one byte at a time. However, BANK1 register zero-adjustment and multicart cartridges need to be considered in ROM dumping code.

Banks 0x20, 0x40 and 0x60 can only be read from the 0x0000-0x3FFF memory area and only when MODE register value is 0b1. Using MODE 0b1 has no undesirable effects when doing ROM dumping, so using it at all times is recommended for simplicity.

Multicarts should be detected using the logo check described earlier, and if a multicart is detected, BANK1 should be considered a 4-bit register in the dumping code.

```
BANK1 = 0x2000
BANK2 = 0x4000
MODE = 0x6000
write_byte(MODE, 0x01)
for bank in range(0, num_banks):
    write_byte(BANK1, bank)
    if is_multicart:
        write_byte(BANK2, bank >> 4)
        bank_start = 0x4000 if bank & 0x0f else 0x0000
else:
        write_byte(BANK2, bank >> 5)
        bank_start = 0x4000 if bank & 0x1f else 0x0000
for addr in range(bank_start, bank_start + 0x4000):
        buf += read_byte(addr)
```

Listing 10.1: Python pseudo-code for MBC1 ROM dumping

MBC2 mapper chip

MBC2 supports ROM sizes up to 2 Mbit (16 banks of 0x4000 bytes) and includes an internal 512x4 bit RAM array, which is its unique feature. The information in this section is based on my MBC2 research, Tauwasser's research notes [6], and Pan Docs [5].

***** Speculation

MBC1 is strictly more powerful than MBC2 because it supports more ROM and RAM. This raises a very important question: why does MBC2 exist? It's possible that Nintendo tried to integrate a small amount of RAM on the MBC chip for cost reasons, but it seems that this didn't work out very well since all later MBCs revert this design decision and use separate RAM chips.

11.1 MBC2 registers

Caveat

These registers don't have any standard names and are usually referred to using one of their addresses or purposes instead. This document uses names to clarify which register is meant when referring to one.

The MBC2 chip includes two registers that affect the behaviour of the chip. The registers are mapped a bit differently compared to other MBCs. Both registers are accessible within 0x0000-0x3FFF, and within that range, the register is chosen based on the A8 address signal. In practice, this means that the registers are mapped to memory in an alternating pattern. For example, 0x0000, 0x2000 and 0x3000 are RAMG, and 0x0100, 0x2100 and 0x3100 are ROMB. Both registers are smaller than 8 bits, and unused bits are simply ignored during writes. The registers are not directly readable.

Register 11.1: 0x0000-0x3FFF when A8=0b0 - RAMG - MBC2 RAM gate register

U	U	U	U	W-0	W-0	W-0	W-⊘
					RAMG	(3:0>	
bit 7	6	5	4	3	2	1	bit 0

bit 7-4 Unimplemented: Ignored during writes

bit 3-0 RAMG<3:0>: RAM gate register

0b1010 = enable access to chip RAM

All other values disable access to chip RAM

The 4-bit MBC2 RAMG register works in a similar manner as MBC1 RAMG, so the upper bits don't matter and only the bit pattern 0b1010 enables access to RAM.

When RAM access is disabled, all writes to the external RAM area 0xA000-0xBFFF are ignored, and reads return undefined values. Pan Docs recommends disabling RAM when it's not being accessed to protect the contents [5].

A Speculation

We don't know the physical implementation of RAMG, but it's certainly possible that the 0b1010 bit pattern check is done at write time and the register actually consists of just a single bit.

Register 11.2: 0x0000-0x3FFF when A8=0b1 - ROMB - MBC2 ROM bank register

U	U	U	U	W-0	W-0	W-0	W-1
					ROMB	(3:0)	
bit 7	6	5	4	3	2	1	bit 0

bit 3-0 ROMB<3:0>: ROM bank register

Never contains the value 0b0000.

If 0b0000 is written, the resulting value will be 0b0001 instead.

The 4-bit ROMB register is used as the ROM bank number when the CPU accesses the 0x4000-0x7FFF memory area.

Like MBC1 BANK1, the MBC2 ROMB register doesn't allow zero (bit pattern 0b0000) in the register, so any attempt to write 0b0000 writes 0b0001 instead.

11.2 ROM in the 0x0000-0x7FFF area

In MBC2 cartridges, the A0-A13 cartridge bus signals are connected directly to the corresponding ROM pins, and the remaining ROM pins (A14-A17) are controlled by the MBC2. These remaining pins form the ROM bank number.

When the 0x0000-0x3FFF address range is accessed, the effective bank number is always 0.

When the 0x4000-0x7FFF address range is accessed, the effective bank number is the current ROMB register value.

	ROM address bits				
Accessed address	Bank number	Address within bank			
	17-14	13-0			
0x0000-0x3FFF	0b0000	A<13:0>			
0x4000-0x7FFF	ROMB	A<13:0>			

Table 11.1: Mapping of physical ROM address bits in MBC2 carts

11.3 RAM in the 0xA000-0xBFFF area

All MBC2 carts include SRAM, because it is located directly inside the MBC2 chip. These cartridges never use a separate RAM chip, but battery backup circuitry and a battery are optional. If RAM is not enabled with the RAMG register, all reads return undefined values and writes have no effect.

MBC2 RAM is only 4-bit RAM, so the upper 4 bits of data do not physically exist in the chip. When writing to it, the upper 4 bits are ignored. When reading from it, the upper 4 data signals are not driven by the chip, so their content is undefined and should not be relied on.

MBC2 RAM consists of 512 addresses, so only A0-A8 matter when accessing the RAM region. There is no banking, and the 0xA000-0xBFFF area is larger than the RAM, so the addresses wrap around. For example, accessing 0xA000 is the same as accessing 0xA200, so it is possible to write to the former address and later read the written data using the latter address.

	RAM address bits
Accessed address	
	8-0
0xA000-0xBFFF	A<8:0>

Table 11.2: Mapping of physical RAM address bits in MBC2 carts

11.4 Dumping MBC2 carts

MBC2 cartridges are very simple to dump. The total number of banks is read from the header, and each bank is read one byte at a time. ROMB zero adjustment must be considered in the ROM dumping code, but this only means that bank 0 should be read from 0x0000-0x3FFF and not from 0x4000-0x7FFF like other banks.

```
ROMB = 0x2100
for bank in range(0, num_banks):
    write_byte(ROMB, bank)
    bank_start = 0x4000 if bank > 0 else 0x0000
    for addr in range(bank_start, bank_start + 0x4000):
        buf += read_byte(addr)
```

Listing 11.2: Python pseudo-code for MBC2 ROM dumping

MBC3 mapper chip

MBC3 supports ROM sizes up to 16 Mbit (128 banks of 0x4000 bytes), and RAM sizes up to 256 Kbit (4 banks of 0x2000 bytes). It also includes a real-time clock (RTC) that can be clocked with a quartz crystal on the cartridge even when the Game Boy is powered down. The information in this section is based on my MBC3 research, and Pan Docs [5].

MBC30 mapper chip

MBC30 is a variant of MBC3 used by Japanese Pokemon Crystal to support a larger ROM chip and a larger RAM chip. Featurewise MBC30 is almost identical to MBC3, but supports ROM sizes up to 32 Mbit (256 banks of 0x4000 bytes), and RAM sizes up to 512 Kbit (8 banks of 0x2000 bytes). Information in this section is based on my MBC30 research.

Warning

The circuit board of Japanese Pokemon Crystal includes a 1 Mbit RAM chip, but MBC30 is limited to 512 Kbit RAM. One of the RAM address pins is unused, so half of the RAM is wasted and is inaccessible without modifications. So, the game only uses 512 Kbit and there is a mismatch between accessible and the physical amounts of RAM.

MBC5 mapper chip

The majority of games for Game Boy Color use the MBC5 chip. MBC5 supports ROM sizes up to 64 Mbit (512 banks of 0x4000 bytes), and RAM sizes up to 1 Mbit (16 banks of 0x2000 bytes). The information in this section is based on my MBC5 research, and The Cycle-Accurate Game Boy Docs [7].

14.1 MBC5 registers

Register 14.1: 0x0000-0x1FFF - RAMG - MBC5 RAM gate register

W-0	W-0	W-0	W-0	W-0	W-0	W-0	W-0	
RAMG<7:0>								
bit 7	6	5	4	3	2	1	bit 0	

bit 7-0 RAMG<7:0>: RAM gate register

0b00001010 = enable access to cartridge RAM All other values disable access to cartridge RAM

The 8-bit MBC5 RAMG register works in a similar manner as MBC1 RAMG, but it is a full 8-bit register so upper bits matter when writing to it. Only <code>0b00001010</code> enables RAM access, and all other values (including <code>0b10001010</code> for example) disable access to RAM.

When RAM access is disabled, all writes to the external RAM area 0xA000-0xBFFF are ignored, and reads return undefined values. Pan Docs recommends disabling RAM when it's not being accessed to protect the contents [5].

***** Speculation

We don't know the physical implementation of RAMG, but it's certainly possible that the <code>0b00001010</code> bit pattern check is done at write time and the register actually consists of just a single bit.

Register 14.2: 0x2000-0x2FFF - ROMB0 - MBC5 lower ROM bank register

W−Ø	W-0	W-0	W-0	W-0	W-0	W-0	W-1	
ROMBØ<7:0>								
bit 7	6	5	4	3	2	1	bit 0	

bit 7-0 ROMB0<7:0>: Lower ROM bank register

The 8-bit ROMB0 register is used as the lower 8 bits of the ROM bank number when the CPU accesses the 0x4000-0x7FFF memory area.

Register 14.3: 0x3000-0x3FFF - ROMB1 - MBC5 upper ROM bank register

U	U	U	U	U	U	U	W-0
							ROMB1
bit 7	6	5	4	3	2	1	bit 0

bit 7-1 Unimplemented: Ignored during writes

bit 0 ROMB1: Upper ROM bank register

The 1-bit ROMB1 register is used as the most significant bit (bit 9) of the ROM bank number when the CPU accesses the 0x4000-0x7FFF memory area.

Register 14.4: 0x4000-0x5FFF - RAMB - MBC5 RAM bank register

				RAMB<3:0>				
bit 7	6	5	4	3	2	1	bit 0	

bit 7-4 Unimplemented: Ignored during writes

bit 3-0 RAMB<3:0>: RAM bank register

The 4-bit RAMB register is used as the RAM bank number when the CPU accesses the 0x-A000-0xBFFF memory area.

MBC6 mapper chip

MBC6 supports ROM sizes up to 16 Mbit (256 banks of 0x2000 bytes), and RAM sizes up to 4 Mbit (128 banks of 0x1000 bytes). The information in this section is based on my MBC6 research.

MBC7

TODO.

HuC-1 mapper chip

HuC-1 supports ROM sizes up to 8 Mbit (64 banks of 0x4000 bytes), and RAM sizes up to 256 Kbit (4 banks of 0x2000 bytes). It also includes a sensor and a LED for infrared communication. The information in this section is based on my HuC-1 research.

HuC-3 mapper chip

HuC-3 supports ROM sizes up to 16 Mbit (128 banks of 0x4000 bytes), and RAM sizes up to 1 Mbit (16 banks of 0x2000 bytes). Like HuC-1, it includes support for infrared communication, but also includes a real-time-clock (RTC) and output pins used to control a piezoelectric buzzer. The information in this section is based on my HuC-3 research.

Instruction set tables

These tables include all the opcodes in the Sharp SM83 instruction set. The style and layout of these tables was inspired by the opcode tables available at pastraiser.com [8].
